

Not a microgrid control function

Overview

A microgrid control system (MCS) is the central intelligence layer that manages the complex operations of a localized power grid. This system integrates diverse power sources, such as solar arrays, wind turbines, and battery storage, collectively known as Distributed Energy Resources. A microgrid is a group of interconnected loads and distributed energy resources within clearly defined electrical boundaries that acts as a single controllable entity with respect to the grid. ² A microgrid can operate in either grid-connected or in island mode, including entirely off-grid. NLR develops and evaluates microgrid controls at multiple time scales. Our researchers evaluate in-house-developed controls and partner-developed microgrid components using software modeling and hardware-in-the-loop evaluation platforms. The Victron's MicroGrid function allows small systems to operate in parallel and communicate with each other to support larger loads in distributed systems. In contrast to conventional power systems, microgrids exhibit greater sensitivity to fluctuations in demand due to their reduced rotating inertia and predominant reliance on.
