

Solar energy storage and heat exchange experiment

Overview

This paper introduces a novel solar-assisted heat pump system with phase change energy storage and describes the methodology used to analyze the performance of the proposed system. Thermal energy storage (TES) refers to heat that is stored for later use—either to generate electricity on demand or for use in industrial processes. Concentrating solar-thermal power (CSP) plants utilize TES to increase flexibility so they can be used as “peaker” plants that supply electricity. This article designs a high-altitude border guard post that can fully utilize the heat absorbed by solar collectors to continuously store thermal energy during the day and stably release heat at night. A mathematical model was established for the key parts of the system including solar evaporator, condenser, phase. Solar hot water systems heat water by solar energy. Such systems consist of solar collectors, a fluid system that absorbs the sun energy, and a reservoir for heat storage for later use. Latent heat storage system is an isothermal nature of storing energy and has advantages of high-energy storage density.
