

The function of the exhaust valve of the generator set

Overview

The cylinder head ports channel air into the combustion chamber and direct exhaust gases out. It controls the opening and closing of the intake valve and the exhaust valve according to the working order of each cylinder of the diesel generator to ensure that there is enough gas in the specified. The use of gas fired, and diesel fueled generators for back-up power and co-generation is increasing due to a higher demand on the current electrical infrastructure, the growing need for backup power and the necessity to improve overall efficiency to ensure uninterrupted power. As the engine burns fuel, it creates exhaust gases that must be vented out of the generator and away from people and equipment. The combustion air passes through a filter and silencer before being compressed by a turbocharger and cooled by the coolant system before entering the individual cylinders. As a universal component, the diesel generator exhaust pipe plays a crucial role in discharging waste gas and smoke in many generator sets.
